LA SPETTROSCOPIA

1814

Joseph Fraunhofer  
(Monaco 1787 - 1826)

# Le linee di Fraunhofer (1814)

↑<sub>D</sub>

Joseph Fraunhofer osservò che lo spettro del Sole, quando sufficientemente disperso, è attraversato da molte sottili linee scure (ne contò più di 500).

W. H. Wollaston le aveva già osservate nel 1802, senza attribuirvi significato.

Fraunhofer studiò gli spettri di molti corpi celesti. Quello della Luna mostrava le stesse linee nere del Sole. Notò che le linee brillanti del Sodio corrispondono alle righe scure D nello spettro solare; ma non fu in grado di darne spiegazione.

*Gustav Robert Kirchhoff*

(1824-1887)

&

*Robert Wilhem Bunsen*

(1811-1899)

Il sodalizio ebbe inizio nel 1850 a Breslavia dove Kirchhoff insegnava e dove, poco dopo, arrivò Bunsen.

Trasferitosi Bunsen ad Heidelberg, Kirchhoff lo seguì nel 1854.

Kirchhoff e Bunsen posero le basi dell'**analisi spettroscopica**, scoprendo che ogni riga spettrale è caratteristica dell'elemento chimico che la emette.

## Space-Time Approach to Quantum Electrodynamics

R. P. FEYNMAN

Department of Physics, Cornell University, Ithaca, New York

(Received May 9, 1949)

In this paper two things are done. (1) It is shown that a considerable simplification can be attained in writing down matrix elements for complex processes in electrodynamics. Further, a physical point of view is available which permits them to be written down directly for any specific problem. Being simply a restatement of conventional electrodynamics, however, the matrix elements diverge for complex processes. (2) Electrodynamics is modified by altering the interaction of electrons at short distances. All matrix elements are now finite, with the exception of those relating to problems of vacuum polarization. The latter are evaluated in a manner suggested by Pauli and Bethe, which gives finite results for these matrices also. The only effects sensitive to the modification are changes in mass and such changes could not be directly observed. Such changes, however, are insensitive to the details of the modification (except at extreme energies). For such purposes, the modification can be taken as the range of the modification; then agree with those of Schwinger. A

and presumably consistent, method is therefore available for the calculation of all processes involving electrons and photons.

The simplification in writing the expressions results from an emphasis on the over-all space-time view resulting from a study of the solution of the equations of electrodynamics. The relation of this to the more conventional Hamiltonian point of view is discussed. It would be very difficult to make the modification which is proposed if one insisted on having the equations in Hamiltonian form.

The methods apply as well to charges obeying the Klein-Gordon equation, and to the various meson theories of nuclear forces. Illustrative examples are given. Although a modification like that

**T**HIS paper should be considered as a continuation of a preceding one on the motion of electrons, neglecting interactions, analyzed, by dealing directly with Hamiltonian differential equations. The technique is applied to include interactions in a unique way to express in simple terms the solution of quantum electrodynamics.

For most practical calculations in quantum electrodynamics the solution is ordinarily expressed as a matrix element. The matrix element is expanded in powers of  $e^2/\hbar c$ , the series corresponding to the inclusion of an increasing number of virtual quanta. It appears that a considerable simplification can be achieved in writing down matrix elements for complex processes. Further, in the expansion can be written down directly from a physical point of view. It is the purpose of this paper to describe how this may be done. We shall also discuss methods of handling the divergent integrals which appear in these matrix elements.

The simplification in the formulae results mainly from the fact that previous methods unnecessarily separated into individual terms processes that were closely related physically. For example, in the exchange of a quantum between two electrons there were two terms depending on which electron emitted and which absorbed the quantum. Yet, in the virtual states considered, timing relations are not significant. Only the order of operators in the matrix must be maintained. We have seen (I), that in addition, processes in which virtual pairs are produced can be combined with others in which only

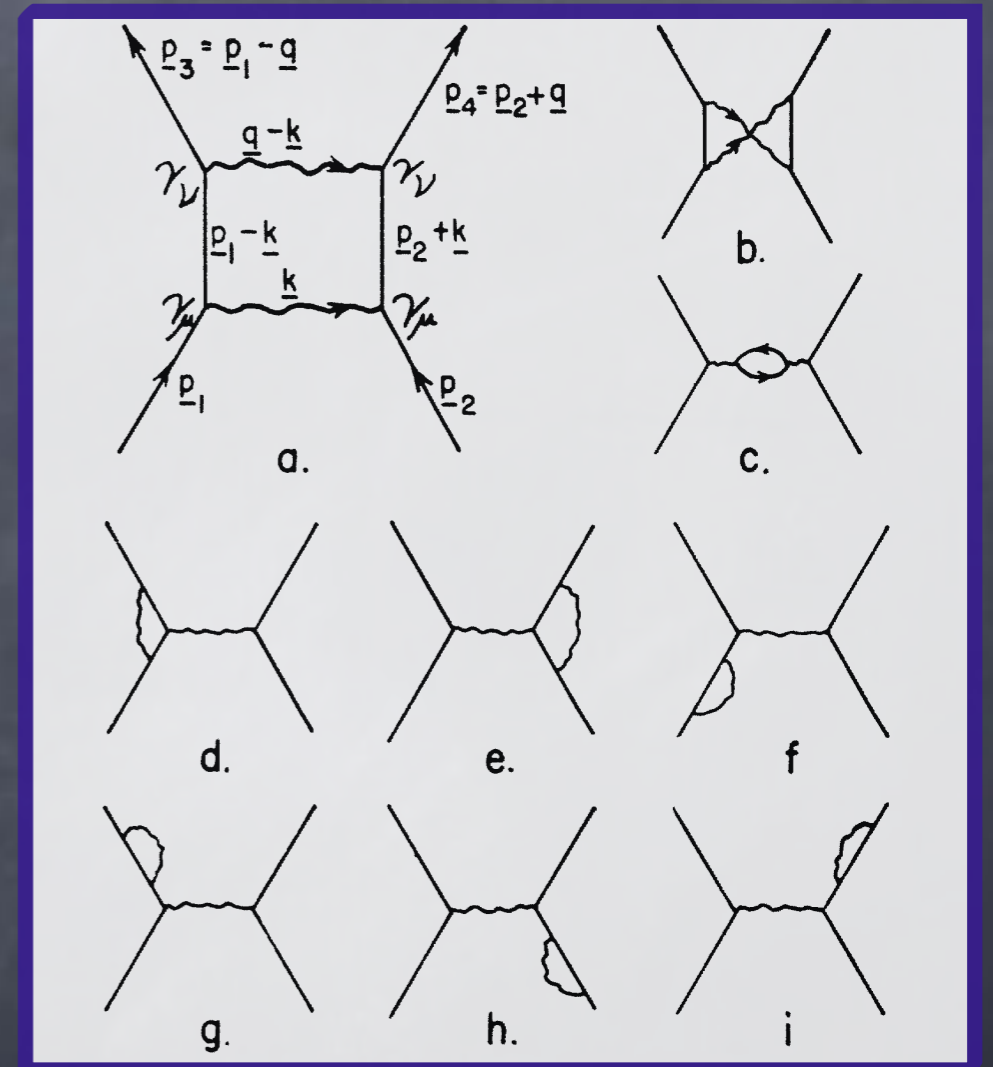

FIG. 1. The fundamental interaction Eq. (4). Exchange of one quantum between two electrons.

Therefore, the self-energy divergent integrals in the interaction between charges is next made, and it is shown that the self-energy is made convergent and corresponds to a correction to the electron mass. After the mass correction is made, other real processes are finite and insensitive to the "width" of the cut-off in the interaction.<sup>3</sup>

Unfortunately, the modification proposed is not completely satisfactory theoretically (it leads to some difficulties of conservation of energy). It does, however, seem consistent and satisfactory to define the matrix

<sup>2</sup> For a discussion of this modification in classical physics see R. P. Feynman, Phys. Rev. 74 939 (1948), hereafter referred to as A.
